

Regression Analysis of the Ames, Iowa Dataset

Stuart Miller, Paul Adams, and Chance Robinson

Master of Science in Data Science, Southern Methodist University, USA

1 Introduction

Ramsey and Schafer^[3]

2 Ames, Iowa Data Set

The Ames, Iowa Data Set describes the sale of individual residential properties from 2006-2010 in Ames, Iowa^[1]. The data was retrieved from the dataset hosting site Kaggle, where it is listed under a machine learning competition named *House Prices: Advanced Regression Techniques*^[2]. The data is comprised of 37 numeric features, 43 non-numeric features and an observation index split between a training set and a testing set, which contain 1460 and 1459 observations, respectively. The response variable (**SalePrice**) is only provided for the training set. The output of a model on the test set can be submitted to the Kaggle competition for scoring the performance of the model in terms of RMSE. The first analysis models property sale prices (**SalePrice**) as the response of living room area (**GrLivArea**) of the property and neighborhood (**Neighborhood**) where it is located. **Add some details on the question 2 variables?**

3 Analysis Question I

3.1 Question of Interest

Century 21 has commissioned an analysis of this data to determine how the sale price of property is related to living room area of the property in the Edwards, Northwest Ames, and Brookside neighborhoods of Ames, IA.

3.2 Modeling

Linear regression will be used to model sale price as a response of the living room area. From the initial exploratory data analysis, it was determined that sale prices should be log-transformed to meet the model assumptions for linearity (see section 5.1), thus improving our models fit and reducing standard error. Additionally, two observations were removed as they appeared to be from a different population than the other observations in the dataset (see section 5.2); therefore, analysis only considers properties with living rooms less than 3500 sq. ft. in area.

We will consider two models: the logarithm of sale price as the response of living room area (1), the reduced model, and the logarithm of sale price as the response of living room area accounting for differences in the three neighborhood of interest (Brookside, Northwest Ames, and Edwards) where Edwards will be used as the reference (2), the full model. An extra sums of square (ESS) test will be used to verify that the addition of `Neighborhood` improves the model.

Reduced Model

$$\mu\{\log(\text{SalePrice})\} = \beta_0 + \beta_1(\text{LivingRoomArea}) \quad (1)$$

Full Model

$$\begin{aligned} \mu\{\log(\text{SalePrice})\} = & \beta_0 + \beta_1(\text{LivingRoomArea}) + \beta_2(\text{Brookside}) + \beta_3(\text{NorthwestAmes}) + \\ & \beta_3(\text{Brookside})(\text{LivingRoomArea}) + \beta_4(\text{NorthwestAmes})(\text{LivingRoomArea}) \end{aligned} \quad (2)$$

The ESS test provides convincing evidence that the interaction terms are useful for the model (p-value < 0.0001); thus, we will continue with the full model.

3.3 Model Assumptions Assessment

The following assessments for model assumptions are made based on Figure 1 and Figure 3:

- The residuals of the model appear to be approximately normally distributed based on the QQ plot of the residuals and histogram of the residuals, suggesting the assumption of normality is met.
- No patterns are evident in the scatter plots of residuals and studentized residuals vs predicted value, suggesting the assumption of constant variance is met.
- While some observations appear to be influential and have high leverage, removing these observations does not have a significant impact on the result of the model fit.
- Based on the scatter plot of the log transform of `SalePrice` vs `GrLivArea`, it appears that a linear model is reasonable (see section 5.1).

The sampling procedure is not known. We will assume the independence assumption is met.

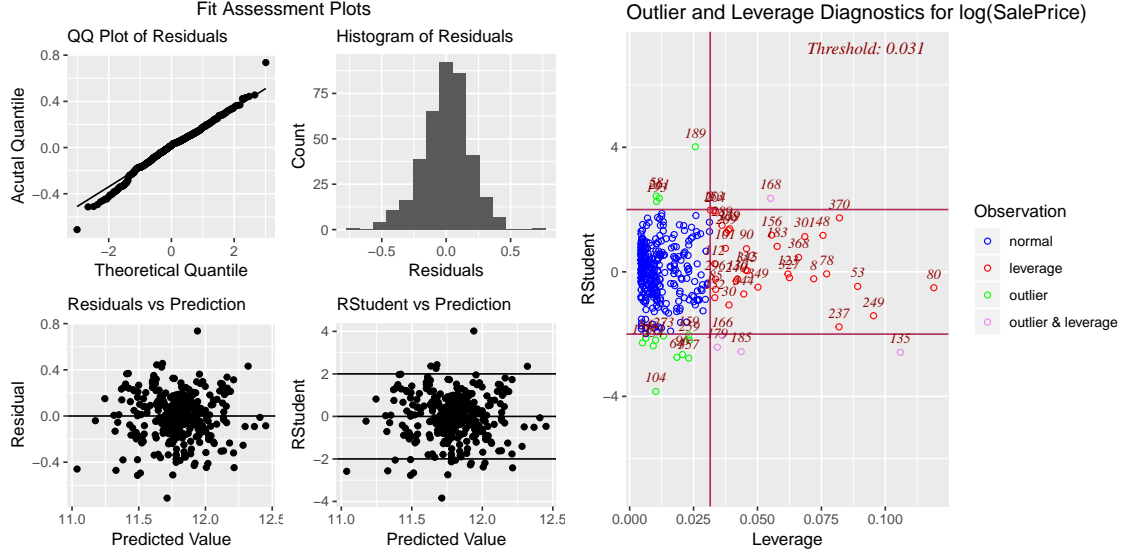

Figure 1: Diagnostic Plots

3.4 Comparing Competing Models

The two models were trained and validated on the training dataset using 10-fold cross validation. The table below summarizes the performance of the models with RMSE, adjusted R^2 , and PRESS. These results show that the full model is an improvement over the reduced model, which is consistent with the result of the ESS test.

Model	RMSE	CV.Press	Adjused.R.Squared
Full Model	0.1910566	12.51675	0.5084024
Reduced Model	0.1988473	13.55835	0.4750767

3.5 Parameters

The following table summerizes the parameter estimates for the full model.

Parameter	Estimate	CI.Lower	CI.Upper
Intercept	11.0254845	10.8861855	11.1647836
GrLivArea	0.0005387	0.0004324	11.1647836
Neighborhood_BrkSide	-0.2338906	-0.4468114	-0.0209698
Neighborhood_NAmes	0.4178562	0.2558923	0.5798200
GrLivArea:Neighborhood_BrkSide	0.0001996	0.0000336	0.0003656
GrLivArea:Neighborhood_NAmes	-0.0002145	-0.0003366	-0.0000924

Where Intercept is β_0 , GrLivArea is β_1 , Neighborhood_BrkSide is β_2 , Neighborhood_NAmes is β_3 , GrLivArea:Neighborhood_BrkSide is β_4 , and GrLivArea:Neighborhood_NAmes is β_5

3.6 Model Interpretation

We estimate that for increase in 100 sq. ft., there is associated multiplicative increase in median price of

- 1.055 for the Edwards neighborhood with a 95% confidence interval of [1.044 , 1.066]
- 1.033 for the Northwest Ames neighborhood with a 95% confidence interval of [1.026 , 1.040]
- 1.077 for the Brookside neighborhood with a 95% confidence interval of [1.063 , 1.090]

Since the sampling procedure is not known and this is an observational study, the results only apply to this data.

3.7 Conclusion

In response to the analysis commissioned by Century 21, the log transform of property sale price was modeled as a linear response to the property living room area for residential properties in Ames, IA. It was determined that it was necessary to include interaction terms to allow for the influence of neighborhood on sale price. Based on the model, there is strong evidence of an associated multiplicative increase in median sale price for an increase in living room area (p-value < 0.0001, overall F-test).

4 Analysis Question II

4.1 Question of Interest

Century 21 has commissioned a second analysis using the same data set, expanded to include as many of the 80 total features, plus the index split, as required to determine the sale price of residential properties across all neighborhoods of Ames, Iowa, beyond only the three - Edwards, Northwest Ames, and Brookside - previously commissioned for analysis.

4.2 Modeling

Restatement of Problem

Through analyzing our variable selection and cross-validation processes - along with our nascent domain knowledge of residential real estate - we ultimately arrived at a multiple linear regression model featuring 11 linear predictor variables and three interaction terms. Specifically, our variable selection process included direct analysis of a correlation plot and a correlation matrix as well as performing forward selection, backward elimination, and stepwise regression. Because many variables contained zeroes that were significant to the factor (for example, bathrooms), we elected to perform logarithmic transformation only to variable **LotArea**, representative of the area of the real estate lot.

In addition to the transformation of **LotArea**, we imputed NA values for 19 variables using a combination of the Data Dictionary provided by Century 21 as well as our domain knowledge.

Type of selection

Forward Selection

Forward selection is a variable selection methodology that begins with a constant mean and adds explanatory variables one-by-one until no further additional predictor variables significantly improve the model's fit. This employs the "F-to-enter" method from the extra-sum-of-squares F-statistic. This was the first method we employed. For this process, we provided the test a starting model with no predictor variables and a model from which terms can be selected, which included all predictor variables available. The process worked forward with selecting one parameter. The suggested model is output below.

```
# Initial Model - Forward Selection
model2.forward.Start <- lm(log(SalePrice)~1,data = train2)

Backward Elimination

Backward elimination is a variable selection methodology that begins with all possible predictor variables and works backward, eliminating variables using all possible combinations until only the best for the fit are provided. This employs the “F-to-remove” method from the extra-sum-of-squares F-statistic. For this process, we provided the test a model with all available predictor variables from which insignificant variables were eliminated. The output is as follows below.

```
##

Stepwise Regression

Stepwise regression is a variable selection methodology that performs one step of forward selection for each step of backward elimination. The steps are repeated, concurrently, until no further predictor variables can be added or removed. This is the third model approach we used. The suggested model is output below.

```
##

Custom Variable Selection

To develop the custom model, we employed a combination of a correlation matrix for quantitative data, analysis of the summarization of the suggested model from stepwise selection, and through direct analysis of the pairs plots. As previously mentioned, our final model included 11 linear terms and three interaction terms. We removed all variables suggested to be removed by the stepwise regression and backward elimination tests, then reprocessed the updated models until forward selection, backward elimination, and stepwise regression were in agreeance with respect to the linear terms. Once this trial-and-error process was completed, we added interaction terms based on domain knowledge and re-applied the forward selection, backward elimination, and stepwise regression methods until only significant terms - both linear and interactive - remained. We then used graphical analysis to visually confirm interaction between the interactive terms remaining.

4.5 Conclusion

A short summary of the analysis

5 Appendix

5.1 Checking for Linearity in SalePrice vs GrLivArea

The scatter plot in Figure 2 shows relationship of SalePrice vs GrLivArea for all three neighborhoods of interest to Century 21. Based on this plot, it does not appear that this relationship meets the assumptions of linear regression, specifically the constant variance assumption. The response will be transformed to attempt to handle the changing variance.

The images below show the scatter plots of log sale price vs living room area (Figure 3). In the image on the right, the scatter plot is shown for each neighborhood. In the image on the left the observations for all three neighborhoods are included. In all cases, a linear model appears to be reasonable to model this data.

Figure 2: Scatter Plot of Sale Price vs Living Room Area

Figure 3: Scatter Plots of Log of Sale Price vs Living Room Area

5.2 Analysis of Influential points

The two outlying observations with living room areas greater than 4000 sq. ft. appear to be from a different distribution than the main dataset. Since these are partial sales, it is possible that the sale prices do not reflect market value. For this reason, we will limit the analysis to properties with less than 3500 sq. ft. 4

Figure 4: Influential Points

5.3 R Code For Analysis 1

```
### Computational Setup
# libraries
library(knitr)
library(kableExtra)
library(tidyverse)
library(olsrr)
library(gridExtra)
library(caret)
library(multcomp)

# load data
train <- read_csv('./data/train.csv')
test <- read_csv('./data/test.csv')

# set a random seed for reproducibility
set.seed(123)

summary(lm(model.formula, data = train.mod))

## Calculate CIs of slopes not in standard table

# get CI for Northwest Ames
confint(glm(model, linfct = "GrLivArea + GrLivArea:Neighborhood_NAmes = 1"))

# get CI for Brookside
confint(glm(model, linfct = "GrLivArea + GrLivArea:Neighborhood_BrkSide = 1"))

```

5.4 R Code For Analysis 2

Include “well commented” code in the appendix!

```

train %>% ggplot(aes(x = (GrLivArea), y = log(SalePrice))) +
  geom_point(alpha = 0.3) +
  labs(title = 'Log of Sale Price vs Living Room Area',
       y = 'Log of Sale Price', x = 'Living Room Area') +
  geom_text(aes(label = ifelse((log(GrLivArea) > 7.75 & log(SalePrice) > 11) |

```

```
(log(SalePrice) > 12.45),  
SaleCondition, '')), hjust=0, vjust=0)
```
